

1.5A SWITCHING REGULATOR

- 1.5A OUTPUT LOAD CURRENT
- 5.1 TO 36V OUTPUT VOLTAGE RANGE
- DISCONTINUOUS VARIABLE FREQUENCY MODE
- PRECISE (+/-2%) ON CHIP REFERENCE
- VERY HIGH EFFICIENCY
- VERY FEW EXTERNAL COMPONENTS
- NO FREQ. COMPENSATION REQUIRED
- RESET AND POWER FAIL OUTPUT FOR MICROPROCESSOR
- INTERNAL CURRENT LIMITING
- THERMAL SHUTDOWN

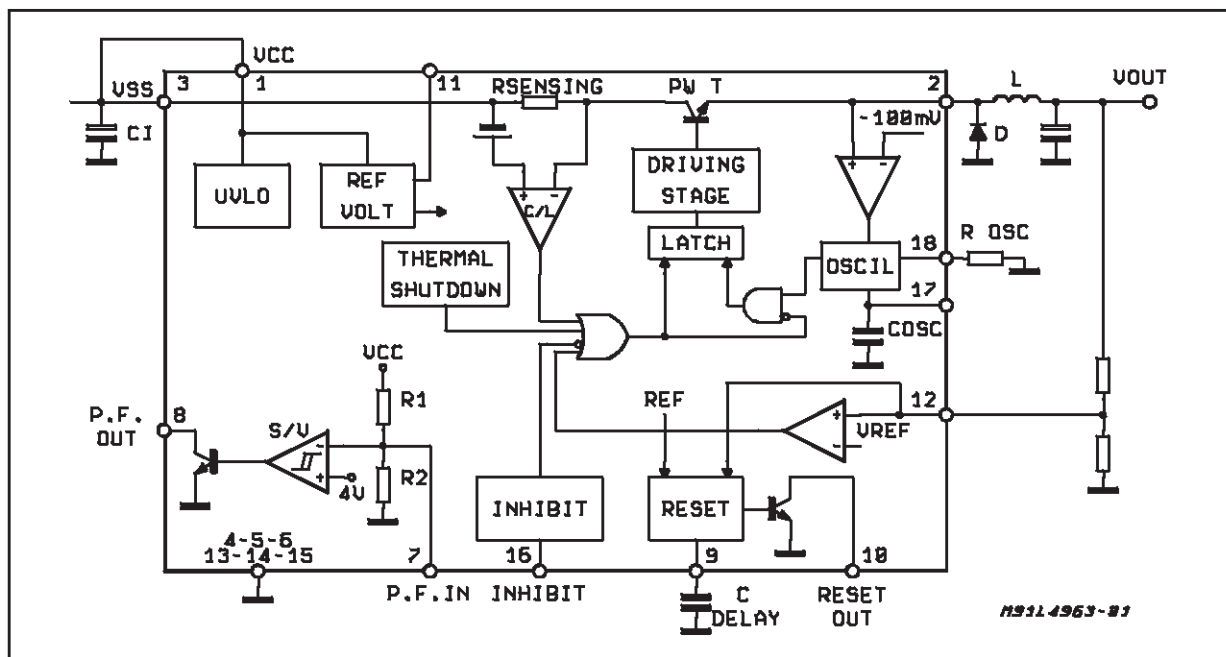

DESCRIPTION

The L4963 is a monolithic power switching regulator delivering 1.5A at 5.1V. The output voltage is adjustable from 5.1V to 36V, working in discontinuous variable frequency mode. Features of the device include remote inhibit, internal current limiting and thermal protection, reset and power fail outputs for microprocessor.

The L4963 is mounted in a 12+3+3 lead Powerdip (L4963) and SO20 large (L4963D) plastic packages and requires very few external components.

PIN FUNCTIONS

SO20L	Power DIP	Name	Description
1	1	SIGNAL SUPPLY VOLTAGE	Must be Connected to pin 3
2	2	OUTPUT	Regulator output
3	3	SUPPLY VOLTAGE	Unregulated voltage input. An internal regulator powers the internal logic.
4, 5, 6, 7 14, 15, 16, 17	4, 5, 6 13, 14, 15	GROUND	Common ground terminal
8	7	POWER FAIL INPUT	Input of the power fail circuit. The threshold can be modified introducing an external voltage divider between the Supply Voltage and GND.
9	8	POWER FAIL OUTPUT	Open collector power fail signal output. This output is high when the supply voltage is safe.
10	9	RESET DELAY	A capacitor connected between this terminal and ground determines the reset signal delay time.
11	10	RESET OUTPUT	Open collector reset signal output. This output is high when the output voltage value is correct.
12	11	REFERENCE VOLTAGE	Reference voltage output.
13	12	FEEDBACK INPUT	Feedback terminal of the regulation loop. The output is connected directly to this terminal for 5.1V operation; it is connected via a divider for higher voltages.
18	16	INHIBIT INPUT	TTL level remote inhibit. A logic low level on this input disables the device.
19	17	C OSCILLATOR	Oscillator waveform. A capacitor connected between this terminal and ground modifies the maximum oscillator frequency.
20	18	R OSCILLATOR FREQ.	A resistor connected between this terminal and ground defines the maximum switching frequency.

CIRCUIT DESCRIPTION (Refer to Block Diagram)

The L4963 is a monolithic stepdown regulator providing 1.5A at 5.1V working in discontinuous variable frequency mode. In normal operation the device resonates at a frequency depending primarily on the inductance value, the input and output voltage and the load current. The maximum switching however can be limited by an internal oscillator, which can be programmed by only one external resistor.

The fundamental regulation loop consists of two comparators, a precision 5.1V on-chip reference and a drive latch. Briefly the operation is as follows: when the choke ends its discharge the catch free-wheeling recirculation filter diode begins to come out of forward conduction so the output voltage of the device approaches ground. When the output voltage reaches -0.1V the internal comparator sets the latch and the power stage is turned on. Then the inductor current rises linearly until the voltage sensed at the feedback input reaches the 5.1V reference.

The second comparator then resets the latch and the output stage is turned off. The current in the choke falls linearly until it is fully discharged, then the cycle repeats. Closing the loop directly gives an output voltage of 5.1V. Higher output voltages are

obtained by inserting a voltage divider and this method of control requires no frequency compensation network. At output voltages greater than 5.1V the available output current must be derated due to the increased power dissipation of the device.

Output overload protection is provided by an internal current limiter. The load current is sensed by a on-chip metal resistor connected to a comparator which resets the latch and turns off the power stage in overload condition. The reset circuits (see fig. 1) generates an output high signal when the output voltage value is correct. It has an open collector output and the output signal delay time can be programmed with an external capacitor. A power-fail circuit is also available and is used to monitor the supply voltage. Its output goes high when the supply voltage reaches a pre-programmed threshold set by a voltage divider to its input from the supply to ground. With the input left open the threshold is approximately equal to 5.1V. The output of the power fail is an open collector.

A TTL level inhibit is provided for applications such as remote on/off control. This input is activated by a low logic level and disables circuits operation.

The thermal overload circuit disables the device when the junction temperature is about 150°C and has hysteresis to prevent unstable conditions.
